TITLE: The lithium-germanium system

SOURCE: AN SSSR. Izvestiya. Neorganicheskiye materialy, v. 2, no. 10, 1966, 1870-1871

TOPIC TAGS: lithium compound, germanium compound, alloy phase diagram, lithium alloy, germanium alloy

ABSTRACT: The phase diagram of the lithium-germanium system was studied by thermal and microstructural analyses in the range of 0-4.5 and 42-100 at. % Ge. At 0-4.5 at. % Ge, the liquidus line corresponds to the crystallization of the compound  $\text{Li}_4\text{Ge}_5$  ( $\text{Li}_{22}\text{Ge}_5$ ), which forms with lithium a eutectic having a melting point of  $184^\circ\text{C}$  ( $2^\circ$  below the melting point of pure lithium). At 42-100 at. % Ge, the liquidus lines intersect at a eutectic point at 50% Ge; the melting point of the eutectic is  $528^\circ\text{C}$ . Microstructural analysis confirmed the presence of eutectics in the alloys. Lithium germanide  $\text{Li}_3\text{Ge}_n$  was synthesized; its powder diagrams had strong lines corresponding to the values  $d = 3.77; 2.33; 2.19; 2.04$  and  $1.95 \text{ \AA}$ , and lines of medium intensity corresponding to the values  $d = 3.37; 1.79; 1.65; 1.45; 1.43; 1.24; 1.16; 1.14; 1.02 \text{ \AA}$ .

TITLE: Physicochemical principles of the hydrometallurgical method of rhenum re-  
fining

SOURCE: Vsesoyuznoye soveshchaniye po problemam reniya, 2d, Moscow, 1962. Reniy  
(rhenum); trudy soveshchaniya. Moscow, Izd-vo Nauka, 1964, 34-39

1975 TAGS: rhenum, rhenum refining, hydrometallurgical refining, molybdenum,  
concentrate, calcium molybdate, potassium perrhenate

ABSTRACT: The authors studied the system  $\text{Ca}(\text{ReO}_4)_2 - \text{CaMoO}_4 - \text{H}_2\text{O}$  at 20 and 75C  
by the isothermal method for the purpose of elucidating the degree and nature of  
the refining of rhenum by the precipitate formed as a result of the neutraliza-  
tion of molybdenum concentrates with calcium oxide. It was found that when  
precipitated by calcium oxide, rhenum and molybdenum are separated into two  
phases: a solid phase and a liquid phase.

AUTHOR: Fedorov, P. N.

TITLE: Concentration of complex titanium-containing ores of the weathering crust

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 3, 1962, 13, abstract 3085  
("Tr. Vses. n.-1. in-ta mineral'n. syr'ya", 1961, no. 6, 140 - 147)

TEXT: The author describes results of concentrating lean Ti-containing complex ores of the weathering crust of the gabbro-anorthosite block. These ores are characterized by the natural break of fine interpenetration and by the isolation of chemically stable mineral products during the formation of the weathering crust ores, and also by friability which almost excludes the necessity of their crushing. Initially the gravitation concentration system was tested. Satisfactory results were obtained at a grain size of -1 to +0.08 mm. Separation in heavy liquids makes it possible to concentrate ilmenite in a fraction with > 3.4 specific weight. The  $TiO_2$  content in this fraction is > 44% at 90 - 95% extraction. Apatite is concentrated in fractions with 2.9 - 3.4 specific weight. The  $P_2O_5$  content in these fractions is 27.4% at 76 - 74% extraction from sands. Prior

Card 1/3

Concentration of complex...

S/137/62/000/003/037/191  
A006/A101

to concentration on tables, the sands were refined to 1 mm size and divided into 2 classes:  $-1+0.25$  and  $-0.25+0.05$  mm, for separation concentration on tables. Ilmenite concentrate is then obtained, containing 35%  $TiO_2$  at 93.1% extraction in the first sample and 25.47 and 85.6% respectively in the second sample. When refining coarse ilmenite concentrates to conditional ones by magnetic separation, the apatite is separated out into a non-magnetic fraction and is then extracted by flotation. Acid processing of ilmenite concentrates brings about almost full elimination of  $P_2O_5$ . Detailed tests were made with a concentration scheme including flotation of initial sands instead of concentration on tables. Flotation was carried out according to a scheme yielding a collective concentrate with subsequent separation on a magnetic separator in a strong magnetic field. Oleic acid was used as a collector. Flotation makes it possible to extract ilmenite and apatite almost completely into the collective concentrate. Magnetic separation of collective concentrates yields ilmenite concentrate containing 48.06 - 43.4%  $TiO_2$  at 80.8 - 86.1% extraction from the ore. The flotation scheme is more compact and makes it possible to concentrate the apatite in one product, i.e. the tails of magnetic separation at 0.25 mm size of the material. Apatite from these products can easily be extracted by flotation into apatite concentrate ( $P_2O_5$  content is 35 - 39% at > 60% extraction). The possibility is shown of almost completely

in the Region of the Caspian Depression," P. V.  
Fedorov

"Byul Mosk Obshch Ispytat Prirody, Otdel Geol"  
Vol 27, No 3, pp 48-62

Fedorov presents data on the high position of  
the ancient shore lines of the Caspian Sea.  
States that deformations of the Baku, Khazar,  
Khvalyn, and Novo-Caspian shore lines make it  
possible to judge the movements of the earth's

229T78

crust on the boundaries of the Caspian depression.  
Vertical movements of various signs, which  
movements developed generally in the Baku and  
Khazar age, gradually died out in the succeeding  
period, he states. Fedorov notes that the movements  
bear a direct and hereditary character.

Title : Conference on the stratigraphy of the deposits of the Quarternary period

Periodical : Izv. AN SSSR. Ser. geog. 6, 99 - 105, Nov - Dec 1954

Abstract : A report is presented of the conference on stratigraphy held in Moscow by geographers and geologists of the Academy of Sciences of the USSR from the 5th to the 16th of May 1954, at which 14 papers were read. A summary is given of each paper. The papers dealt with the general subject of the formation of the uniform stratigraphic rocks for the Quarternary deposits, the stratigraphy of the Quarternary deposits of the Central and northwestern regions and the stratigraphy of the Quarternary deposits in the southern regions of Soviet territory in Europe. Three excursions were made for observations.

**AUTHOR:** FEDOROV, P.V.  
**TITLE:** New Data on the Stratigraphy of the New-Caspian Deposits of West Turkmenia.  
 (Novyye dannyye po stratigrafii novokaspiyskikh otlozheniy Zapadnoy Turkmenii. Russian).  
**PERIODICAL:** Doklady Akademii Nauk SSSR, 1957, Vol 113, Nr 6, pp 1342 - 1343 (U.S.S.R.)  
**ABSTRACT:** The profile which recently appeared on the north western coast of the isle of Cheleken in consequence of washing out shows under a yellowish mass of layer of sand (4-5 m thick) gray strata of marine sands with Cardium edule, L. Monsdacna caspia Eichw., Adaona pliata Eichw. etc.. Their thickness fluctuates between 0,6 - 0,7 towards the sea and 0,2-0,1 towards the land where they gradually thin out and become coarse-grained. These sands rest on an eroded surface of inclined strata of sand with rare shell fragments: Dreissena rostriformis Lindh., Didaona preatrigonoides Nal., Theodoxus pallasii and others more. The stratification of the sands lying under the New-Caspian marine strata is of aeolian character. This obviously proves the fact that their formation is connected due to the influence of upper-Khvalynio marine deposits. Besides, yellowish sands with C.edule, Didaona crassa etc. are found to lean on the continental mass of the chya and sands which cover the

Card 1/3

New data on the Stratigraphy of the New-Caspian Deposits of West Turkmenia.

gray sands with C. edule etc. They form terrace (5,5 - 6 m, minus 22 m sea level) which is well known on all Caspian coasts and is the maximum of the New-Caspian transgression. Since the deposits of the latter are separated from the lower stratum with C. edule by a relatively thick mass of continental deposits, this proves another and earlier transgression. The coast line of the old transgression is hardly deformed in a height of 4 m by tectonic motions. The transgression level of the sea was deeper at the beginning of the New-Caspian age than in the following phase, but it exceeded the recent level. Recent investigations carried out by A.I. Dzents-Litovskiy in Kara-Bogaz-Gol showed that the New-Caspian deposits are a mass of sands and clays which are separated by salt layers. The alternation of deposits of different mechanical composition and salt content speak of repeated shifts of the sea coast line. In the Kara-Bogaz-Gol this led to a transformation into a salty lagoon and even in a separated drying salt lake and once also into an open gulf. The profile of the northern part of the western coast of Cheleken relates part of Caspian history during the New-Caspian transgression. It is quite probable that the sands with C. edule correspond to one of the earliest transgressions of the sea which fol-

lowed the post-Khvalynio (Mangyshlak) regressive phase. Concerning the absolute age of the level it must be said that the determinations hitherto made must be looked upon as purely relative. (4 Slavic references).

TITLE: The Stratigraphic Importance of Caspian Quaternary Mollusks in the Light of New Data (Stratigraficheskoye znachenie kaspiyskikh chetvertichnykh mollyuskov v svete novykh dannyykh)

PERIODICAL: Byulleten' Moskovskogo obshchestva ispytateley prirody, Otdel geologicheskoy, 1958, Nr 3, pp 158 - 159 (USSR)

ABSTRACT: This is a resume of a lecture given on Mar 14, 1958. To the present time, stratigraphic data on Quaternary deposits of the Caspian region was based on mollusks, mainly Didacna Eichw. However, it has been found that many of these guiding faunal fossils occurred in various stratigraphic levels. Therefore, the age of deposits can not be judged exclusively by the presence of "guiding" species, without taking living conditions, stratigraphy and geomorphology into consideration. In spite of an abundance, and frequent predominance of local forms as well as ecologic varieties, it is possible by carefully collecting faunal fossils and by simultaneously considering the living conditions and quantitative relations, to single out reliable guiding groups and specimens typical of certain strata found within the region of the Caspian (and even Black Sea)

SOV/20-124-5-47/62

TITLE:

On Fluctuations of the Level of the Black Sea in the Post-glacial Time (O kolebaniyakh urovnya Chernogo morya v poslelednikovoye vremya)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 124, Nr 5, pp 1127-1129 (USSR)

ABSTRACT:

The fluctuations mentioned in the title were synchronous and equal to those of the ocean. The stage known in the Mediterranean as Nice transgression which during the subboreal (xero-thermal) period corresponded to the high level of the ocean (Flemish on West European coasts, Littorina stage of the Baltic) could be observed in the Black Sea only by few scientists (Refs 2,3). The pieces of a deeply lying marine terrace and shell accumulations above the shore were found as purely recent formations (Ref 1). In a special investigation (1955), however, also the most recent terrace was found (height: 3-5 m). The mollusc fauna of its sediments indicates a stronger halophilism of the species than that of the recent fauna (Ref 4). This terrace is regarded as a trace of the Old Black-Sea transgression (Old Pontic? Old Euxinian?)

Card 1/3

On Fluctuations of the Level of the Black Sea in the Postglacial Time SCV/20-124-5-47 /62

(drevnechernomorskiy etap) which followed the regression of the New Euxine period (Ref 1). It could be called a Phanagoric regression since the ruins of the ancient Greek colonies are now 1-2 m below the recent sea level. The observations made by the author together with A. R. Geptner (1957-58) on the Taman and Kerch' peninsulae as well as on the Caucasian coast completed the material which had hitherto been collected. The author reconstructs the last pages of the geological history of the Black Sea as follows: towards the end of the New Euxine period the sea level began to rise. At the beginning of this postglacial transgression and the increase in the salt content (called Old Black-Sea Epoch, Ref 1) the level was below the recent one. The sea was inhabited by relics of Caspian fauna and by representatives of Mediterranean flora extruding them. The developing transgression raised the level up to 2-2.5 m above the recent one. The fauna here was somewhat more halophilous than the recent one. This is the New Black-Sea Stage of the author (Ref 4). Its terrace corresponds to the Nice and other Western European terraces

Card 2/3

On Fluctuations of the Level of the Black Sea in the Postglacial Time SOV/20-124-5-47/62

(as mentioned above). The Nice transgression was connected with the raise of the ocean level due to the thawing glaciers during the subboreal time. The following Phanagoric (fanagoriyskaya) regression was followed by a new transgression, probably of very short duration. Its level was about 1 m above the recent one. According to the author, this most recent transgression of the Black Sea which had covered the remains of the castle of Nymphaea is called nymphaean (Fig 1). There are 1 figure and 4 Soviet references.

TITLE:

On the Chaudinskiye Sediments in the Region of Cape Idukopas

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 127, Nr 3,  
pp 663 - 664 (USSR)

ABSTRACT:

Marine Chaudinskiye sediments with a typical mollusc fauna are known from a limited number of places (Refs 1,4,6). It was assumed that they exist near Tuapse on the Caucasian coast (Ref 2). The highest (100 m) marine terrace in Abkhaziya (Ref 3) was classified as belonging to this age. In the summer 1958 the author (together with A. P. Geptner) investigated conglomerates and (somewhat higher) alternations of beds of a pebble conglomerate with interstrata and lenses of a calcareous and conchoidal detritus. These deposits are solidly cemented and enriched with calcium carbonate. Their thickness amounts to 2 - 2.5 m. The mollusc fauna found in the calcareous beds and lenses prove the Chaudinskiy (Chaudinsko-Bakinskiy) age of the rocks containing them. The sole is situated at an absolute altitude of 42 - 43 m. Thus the Chaudinskaya terrace is here half as high as in the south-west of Tuapse, in Abkhaziya and Guriya

Card 1/3

On the Chaudinskiye Sediments in the Region of Cape  
Idukopas

SOV/20-127-3-53/71

where it is situated at an altitude of 100-110 m. The position of the Chaudinskaya terrace at the place mentioned is related to a certain structural stage. This reflects the transition of the highest elevation zone of the western part of the Caucasus Mountains towards the zone of a less high elevation and then to a depression zone. A similar abrupt difference of altitudes of the marine Bakinskiy and Khazarskiye terraces can also be observed in the eastern part of the Caucasus Mountains (Ref 5). On account of the findings mentioned the Chaudinskiye sediments of the classical section of the Kerch' Peninsula are assumed to be related to the corresponding sediments in Guriya. There are 6 Soviet references.

TITLE:

Some Recent Data on the Uzunlar Deposits on the Caucasian Coast of the Black Sea (Nekotoryye novyye dannyye ob Uzunlarskikh otlozheniyakh Kavkazskogo poberezh'ya Chernogo morya)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 127, Nr 4, pp 862-864 (USSR)

ABSTRACT:

The Uzunlar sediments, for the first time disclosed on the Kerch' Peninsula (Ref 1), are known to exist also along the Caucasian Coast (Refs 1,2). South-east of Dzhubg' (near Tenginka) they are connected with the old-Euxinian terrace. Without discussing the finds in Guriya, the author mentions the results obtained by him and A. R. Geptner in 1958. The old-Euxinian Uzunlar terrace has a considerable width and is distinctly pronounced in the relief of the entire Caucasian Coast of the Black Sea. It forms the present outlines of the transverse coastal section. Thus it may be assumed that the respective developmental phase of the Black Sea lasted for a considerable amount of time. The situation of the old coastal line serves only for an indirect determination. Its altitude

Card 1/3

SOV/20-127-4-39/60

Some Recent Data on the Uzunlar Deposits on the Caucasian Coast of the Black Sea

was probably near 50 m above sea level. The terrace under discussion is separated from the high Karangatskaya Terrace (25 m high) and the lower Karangatskaya Terrace (12 m high) by a sharp, abraded step. The stratigraphic position of the Uzunlar and its interrelations to the Karangatskiya sediments has not yet been completely explained. According to reference 1 these sediments reflected the initial phase of the salification of the old-Euxinian waters. This was caused by the entering of Mediterranean water into the Black Sea depression. Further salification led to the formation of an abundant Karangatskaya fauna in the sea. Nevertheless, opinions on the interrelations mentioned differ considerably. The assertions mentioned by the author, however, prove those of references 1 and 5 convincingly enough. At present it is still difficult to judge the importance of the interruption between the Uzunlar and the Karangat. The author assumes that certain changes of maritime conditions played a certain role in addition to purely structural causes. There are 4 Soviet references.

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 4, 1966, 116

TOPIC TAGS: fuel carburetor, internal combustion engine, transducer

ABSTRACT: This Author Certificate presents a carburetor for internal combustion engines. The carburetor contains a diffuser with atomizer which supplies fuel from a hermetically sealed float chamber at a rate dependent on the pressure difference between the chamber and the diffuser (which are connected by a variable resistance channel (see Fig. 1). To increase economy, the channel is equipped with a fast-
